OBJECT-ORIENTED PROGRAMMING

5. MEMORY MANAGEMENT AND CLASS ORGANIZATION

Nguyen Thi Thu Trang
trangntt@soict.hust.edu.vn

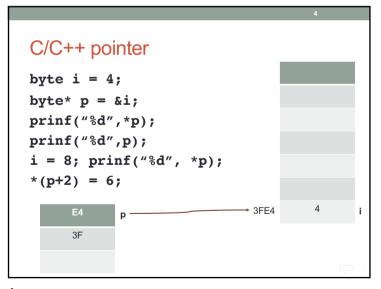

# 1. Memory management in Java

- Java does not use pointer, hence memory addresses can not be overwritten accidentally or intentionally.
- The allocation or re-allocation of memory, management of memory that is controlled by JVM, are completely transparent with developers.
- Developers do not need to care about the allocated memory in heap in order to free it later.

3. Utility classes in Java

3

1

1.1. Heap memory (2)

String s = new String("hello");

String t = s;

• Heap memory is used to write tinformation created by new operator.

Heap Memory

Heap Memory

6

# 1.3. Garbage collector (gc)

- The garbage collector sweeps through the JVM's list of objects periodically and reclaims the resources held by unreferenced objects
- All objects that have no object references are eligible for garbage collection
- References out of scope, objects to which you have assigned null, and so forth
- The JVM decides when the gc is run
- Typically, the gc is run when memory is low
- May not be run at all
- Unpredictable timing

7

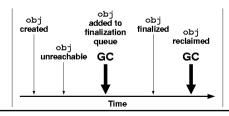

Working with the garbage collector

- You cannot prevent the garbage collector from running, but you can request it to run soon
- System.gc();
- This is only a request, not a guarantee
- The finalize() method of an object will be run immediately before garbage collection occurs
- This method should only be used for special cases (e.g. cleaning up memory allocation from native calls)
   because of the unpredictability of the garbage collector
- Things like open sockets, files, and so forth should be cleaned up during normal program flow before the object is dereferenced

9

finalize() method

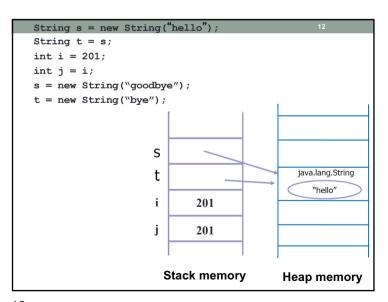

- Any class has method finalize() that is executed right after the garbage collection process takes place (considered as destructor in Java despite not)
- Override this method in some special cases in order to "self-clean" used resources when objects are freed by gc
- E.g. pack socket, file,... that should be handled in the main thread before the objects are disconnected from reference.

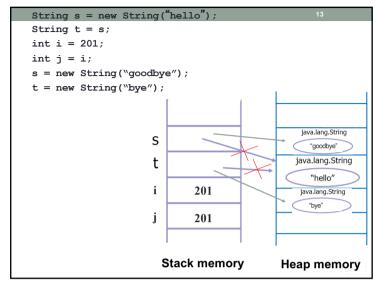

Java destructors?

- Java does not have the concept of a destructor for objects that are no longer in use
- Deallocation of memory is done automatically by the JVM through the finallize() method
- A background process called the garbage collector reclaims the memory of unreferenced objects
- The association between an object and an object reference is severed by assigning another value to the object reference, for example:
- objectReference = null;
- An object with no references is a candidate for deallocation during garbage collection

10

11

# 1.4. Object comparison

15

• **Primitive data types:** == checks whether their values are the equal

```
int a = 1;
int b = 1;
if (a==b)... // true
```

 Objects: == checks whether two objects are unique ~ whether they refer to the same object

```
Employee a = new Employee(1);
Employee b = a;
if (a==b)... // true

Employee a = new Employee(1);
Employee b = new Employee(1);
if (a==b)... // false
```

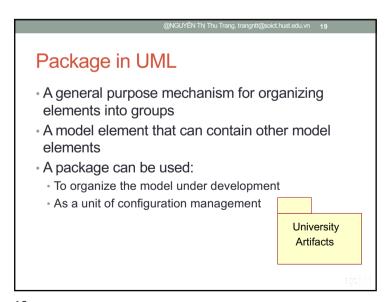

Memory Management in Java (Method and variables)

14

16

# equals() method

- For primitive data types → does not exist.
- For objects: every object has this method
- o Compares values of objects
  public class Equivalence {
   public static void main(String[] args) {
   Integer n1 = new Integer(47);
   Integer n2 = new Integer(47);
   System.out.println(n1 == n2);
   System.out.println(n1.equals(n2));
  }

18

# Package in OOP and Java

- Composed of a set of classes that have some logic relation between them
- Considered as a directory, a place to organize classes in order to locate them easily
- A package can also contain another package
  - com.google: "com" package contains "google" package
- Example in Java:
- Some packages already available in Java: java.lang, javax.swing, java.io...
- Packages can be manually defined by users
- Separated by ".", convention for naming package: lowercase
- Example: package oolt.hedspi;

10.5

20

Why Package?

 Organize and locate easily the classes and use classes in a appropriate manner

- Avoid conflict in naming classes
- Different packages can contains classes with same name
- Protect classes, data and methods in a larger area compared to relation between classes

21

Package declaration

· Declaration syntax:

package package.name;
access\_modifier class ClassName{
 // Class body
}

- •access modifier:
  - public: Class can be accessed from anywhere, including outside its package.
  - private: Class can only be accessed from inside the class
  - None (default): Class can be access from inside its package

A Package Can Contain Classes

The package, University Artifacts, contains one package and five classes.

Student Artifacts

Course Schedule

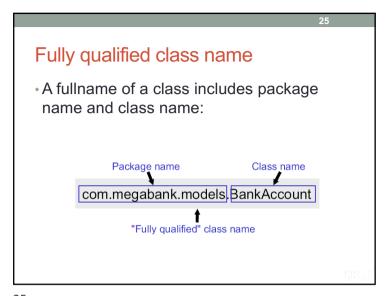

Student CourseOffering

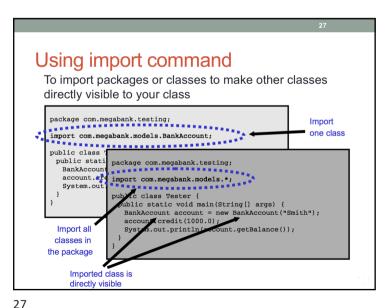

22

Member declaration of class

 Class members have access definition similarly to the class.

	public	None	private
Same class			
Same package			
Different package			

2.1. References between classes In the same package: use class name • In different packages: must provide the full-name of class defined in other packages. Example: package oolt.hedspi; public class HelloNameDialog{ public static void main(String[] args){ String result; result = javax.swing.JOptionPane. showInputDialog("Please enter your name:"); javax.swing.JOptionPane. showMessageDialog(null, "Hi "+ result + "!");

26

```
2.2. Packages in Java
   •java.applet
                               •javax.rmi
   •java.awt
                               • javax. security
   •java.beans
                               • javax.sound
   •java.io
                               •javax.sql
   • iava.lang
                               • iavax.swing
   •java.math
                               • javax. transaction
   •java.net
                               •javax.xml
   •java.nio
                               •org.apache.commons
   •java.rmi
                               •org.ietf.jgss
   •java.security
                              org.omg.CORBA
   •java.sql
                               •org.omg.IOP
   •java.text
                               •org.omg.Messaging
   •java.util
                               •org.omg.PortableInterceptor
   • javax.accessibility
                               •org.omg.PortableServer
   •javax.crypto
                               •org.omg.SendingContext
   •javax.imageio
                               •org.omg.stub.java.rmi
   • javax.naming
                               org.w3c.dom
   •javax.net
                               org.xml
   •javax.print
```

# Basic packages in Java

### · java.lang

- Provides classes that are fundamental to the design of the Java programming language
- Includes wrapper classes, String and StringBuffer, Object, and so on
- · Imported implicitly into all classes

#### · java.util

 Contains the collections framework, event model, date and time facilities, internationalization, and miscellaneous utility classes

### · java.io

 Provides for system input and output through data streams, serialization and the file system

1010

29

## Sample package: java.lang

#### Basic Entities

· Class, Object, Package, System

#### Wrappers

· Number, Boolean, Byte, Character, Double, Float, Integer, Long, Short, Void

#### · Character and String Manipulation

· Character.Subset, String, StringBuffer, Character.UnicodeBlock

#### Math Functions

· Math, StrictMath

#### Runtime Model

 Process, Runtime, Thread, ThreadGroup, ThreadLocal, InheritableThreadLocal, RuntimePermission

#### JVM

31

· ClassLoader, Compiler, SecurityManager

#### Exception Handling

- · StackTraceElement, Throwable
- · Also contains Interfaces, Exceptions and Errors

A-S

Basic packages in Java

## · java.math

 Provides classes for performing arbitrary-precision integer arithmetic and arbitrary-precision decimal arithmetic

### java.sql

 Provides the API for accessing and processing data stored in a data source (usually a relational database)

### java.text

 Provides classes and interfaces for handling text, dates, numbers, and messages in a manner independent of natural languages

### javax.swing

Provides classes and interfaces to create graphics

1657

30

Content

- 1. Memory management in Java
- 2. Class organization
- 3. Utility classes in Java

1050

## 3.1. Wrapper class

- Primitives have no associated methods; there is no behavior associated with primitive data types
- Each primitive data type has a corresponding class, called a wrapper
- Each wrapper object simply stores a single primitive variable and offers methods with which to process it
- Wrapper classes are included as part of the base Java API

33

## Converting data type

- Use toString() to convert number values to string.
- Use <type>Value() to convert an object of a wrapper class to the corresponding primitive value

```
Float objF = new Float("4.67");
float f = objF.floatValue(); // f=4.67F
int i = objF.intValue(); //i=4
```

 Use parse<type>() and valueOf() to convert string to number values.

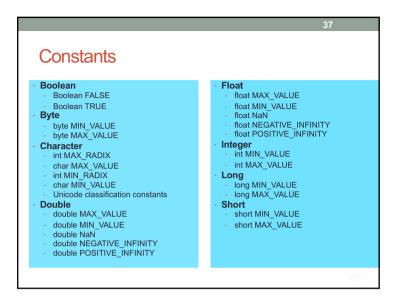

```
int i = Integer.parseInt("123"); //i=123
double d = Double.parseDouble("1.5"); // d=1.5
Double objF2 = Double.valueOf("-36.12");
long l = objF2.longValue(); // l=-36L
```

Wrapper classes

Primitive Type	Wrapper Class	
boolean	Boolean	
byte	Byte	
char	Character	
double	Double	
float	Float	
int	Integer	
long	Long	
short	Short	

34

39

3.2. String
The String type is a class, not a primitive data type
A String literal is made up of any number of characters between double quotes:

String a = "A String";
String b = "";

A String object can be initialized in other ways:

String c = new String();
String d = new String("Another String");
String e = String.valueOf(1.23);//"1.23"
String f = null;

```
Example

double d = (new Integer(Integer.MAX_VALUE)).

doubleValue();

System.out.println(d); // 2.147483647E9

String input = "test 1-2-3";
int output = 0;
for (int index = 0; index < input.length(); index++)

{
   char c = input.charAt(index);
   if (Character.isDigit(c))
   output = output * 10 + Character.digit(c, 10);
}
System.out.println(output);
```

38

```
a. String concatenation

The + operator concatenates Strings:

String a = "This" + " is a " + "String";

//a = "This is a String"

There are more efficient ways to concatenate Strings
(this will be discussed later)

Primitive data types used in in a call to println() are automatically converted to String

System.out.println("answer = " + 1 + 2 + 3);

System.out.println("answer = " + (1+2+3));

Do two above commands print out the same output?
```

```
b. Methods of String
 Strings are objects; objects respond to messages

✓ Use the dot (.) operator to send a message

✓ String is a class, with methods

 String name = "Joe Smith";
 name.toLowerCase();
                                 // "joe smith"
 name.toUpperCase();
                                 // "JOE SMITH"
 "Joe Smith ".trim();
                                 // "Joe Smith"
 "Joe Smith".indexOf('e');
                                 // 2
 "Joe Smith".length();
                                 // 9
  "Joe Smith".charAt(5);
                                 // 'm'
                                 // "mith"
 "Joe Smith".substring(5);
 "Joe Smith".substring(2,5); // "e S"
```

```
C. Comparing two Strings (2)

String s1 = new String("Hello");
String s2 = s1;
(s1==s2) returns true

String s1 = new String("Hello");
String s2 = new String("Hello");
(s1==s2) returns false
s1.equals(s2) return true

s1 Hello
```

c. String comparison

oneString.equals(anotherString)

Tests for equivalence
Return true or false

if ("Joe".equals(name))
name += "Smith";

oneString.equalsIgnoreCase(anotherString)
Case insensitive test for equivalence

boolean same = "Joe".equalsIgnoreCase("joe");

oneString == anotherString is problematic
Compare two objects

42

```
String Literal vs. String Object
                                      // String literal
• String s1 = "Hello";
• String s2 = "Hello";
                                      // String literal
• String s3 = s1; // same reference
• String s4 = new String("Hello"); // String object
• String s5 = new String("Hello"); // String object
• String s6 = s5;
• s5 = new String("Goodbye");
s1 = "Goodbye";
                                      s4 🗨 s5 🗨
                                            s4:String
                                                    s5:String
                                            "Hello"
                                                    "Hello"
                       "Goodbye"
                                             Strling("Goodbye")
                      Common pool for String literals
```

## 3.3. StringBuffer/StringBuilder

- String is an immutable type:
- Object does not change the value after being created → Strings are designed for not changing their values.
- Concatenating strings will create a new object to store the result → String concatenation is memory consuming.
- StringBuffer/StringBuilder is a mutable type:
  - · Object can change the value after being created
- => String concatenation can get very expensive, only use in building a simple String

1650

45

47

## 3.3. StringBuffer (3)

- •StringBuffer:
- Provides String object that can change the value → Use StringBuffer when:
  - Predict that characters in the String can be changed
- When processing a string, e.g. reading text data from a text file or building a String through a loop
- Provides a more efficient mechanism for building and concatenating strings:
- String concatenation is often done by compiler in class **StringBuffer**

iński)

3.3. StringBuffer (2)

s
t

java.lang.String

java.lang.String

"hello"

"goodbye"

String s = new String("hello");

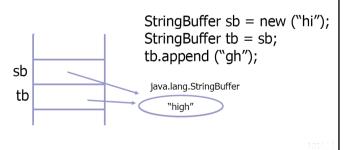

String t = s;

s = new String("goodbye");

46

# 3.3. StringBuffer (4)

 Changing attribute: If an object is changed, all the relations with the object will receive the new value.

48

```
3.3. StringBuffer (5)

• If we create a String by a loop, we should use stringBuffer

StringBuffer buffer = new StringBuffer(15);
buffer.append("This is ");
buffer.append("String");
buffer.insert(7," a");
buffer.append('.');
System.out.println(buffer.length()); // 17
System.out.println(buffer.capacity()); // 32
String output = buffer.toString();
System.out.println(output); // "This is a String."
```

51

#### 3.4. Math class sin () cos () tan () asin () · java.lang.Math provides static acos () data: atan () toRadians () toDegrees() exp() Math constants: • log () • sqrt () • IEEEremainder () Math.E o ceil ( ) floor ( ) Math.PI • rint () • atan2 () • Math functions: o pow () round () round () · max, min... initRNG() random() · abs, floor, ceil... abs ( )abs ( )abs ( ) sqrt, pow, log, exp... max ( ) · cos, sin, tan, acos, asin, atan... max() max () random min ( ) ● min () ● min () ▲ <dinit> ()

```
Example of reading from a file

String str = "";
for (int i=0; i<1.000.000; i++){
   //read a line from a file
   str += line;
}

StringBuffer str = "";
for (int i=0; i<1.000.000; i++){
   //read a line from a file
   str.append(line);
}
```

50

```
sin ()cos ()
3.4. Math class (2)
                                                               tan ()asin ()
                                                               acos ()

atan ()
toRadians ()
toDegrees ()

    Most of functions receive arguments with type

 double and also return values with tye
                                                               exp()
  double
                                                               sqrt ( )
  · Example:

    IEEEremainder ( )

                                                               o ceil ( )
                                                               o floor ()
                                                               o rint ()
o atan2 ()
o pow ()
Math.pow (Math.E,
                                                               o round ()
                                                               oround()
        Math.sqrt(2.0*Math.PI))
                                                               random ()
                                                               abs ()abs ()
Math.exp(Math.sqrt(2.0*Math.PI))
                                                               abs ()
                                                               ■ max ( )
                                                               ■ max ( )
                                                               max ( )
                                                               max ( )
                                                               min ( )
                                                               min ( )

    min ( )
```
